Abstract

To determine the diversity of species and subspecific taxa of diatoms of the genus *Lyrella* found in subtidal sediments of Laguna Guerrero Negro (LGN), BCS-BC (Mexico), samples from 4 seasons were analyzed. Twenty-one species and sub-specific taxa of *Lyrella* are here recorded within a floristic list of 232 identified epipelagic diatom taxa. Seven *Lyrella* taxa are new records for the Mexican coasts and 12 for the northwestern Mexican region. Additionally, we are proposing 6 transfers of taxa into *Lyrella* that remained hitherto in the genus *Navicula*. Morphometric and meristic data, and an iconographic reference are provided. Environmental conditions in the lagoon favor the diversity and abundance of *Lyrella* species and sub-specific taxa. Thus, LGN is proposed as a diversity hotspot for this genus. Lack of floristic studies on benthic diatoms in much of the Mexican coasts precludes insight of their ecology and distribution. However, continuous floristic surveys should eventually allow precise definition of their biogeographic affinities.

Keywords: Biosphere reserve; Epipelagic diatoms; Guerrero Negro; *Navicula*; New combinations

Resumen

Con el objetivo de determinar la diversidad de especies y taxones subespecíficos de *Lyrella* presentes en sedimentos del submareal en la laguna Guerrero Negro, BCS-BC (México), se analizaron muestras de 4 estaciones. Se registraron 21 especies y taxones subespecíficos de *Lyrella* como parte de una lista florística de 232 taxones epipélicos. Siete de estos taxones son nuevos registros para las costas mexicanas y 12 para la región norteña de México. Además, se proponen 6 transferencias de taxones que hasta ahora eran consideradas dentro del género *Navicula* hacia el género *Lyrella*. Se proporcionan datos morfométricos y merísticos, así como una referencia iconográfica. Dado que las condiciones ambientales propias de la laguna favorecen la diversidad y abundancia de especies y taxones subespecíficos de *Lyrella*, laguna Guerrero Negro se propone como un hotspot de diversidad para este género. Aunque la escasez de estudios florísticos sobre diatomeas bentónicas en las costas mexicanas limita la perspectiva ecológica y biogeográfica que ameritan, se confía en que la continuidad de estudios florísticos reditúe bases para definir sus afinidades biogeográficas.

Introduction

Studies on benthic diatoms (Bacillariophyceae) from the Baja California Peninsula date back 3 decades to the first list of benthic diatoms (Hernández-Becerril & Álvarez-Borrego, 1983) followed by a more complete study on epiphytic forms thriving on eelgrass *Zostera marina* Linneo (Siqueiros-Beltrones & Ibarra-Obando, 1985; Siqueiros-Beltrones, Ibarra-Obando, & Loya-Salinas, 1985). Further studies of benthic diatoms included other substrata, such as sediments from hypersaline environments (Brown, Margulis, Ibarra, & Siqueiros, 1985; López-Fuerte & Siqueiros-Beltrones, 2006; López-Fuerte, Siqueiros-Beltrones, & Navarro, 2010; Siqueiros-Beltrones, 1988, 1990; Siqueiros-Beltrones & Morzaria-Luna, 1999; Siqueiros-Beltrones & Sánchez-Castrejón, 1999; Siqueiros-Beltrones, Ibarra-Obando, & Poumián-Tapia, 1991), and highly productive ecosystems (Hernández-Almeida & Siqueiros-Beltrones, 2012; Siqueiros-Beltrones, 2006). Although these studies recorded over a 1,000 species for this region, the many distinct ecosystems along the latitudinal gradient and various types of substrata are yielding taxa not seen before, or showing that hitherto rare taxa may occur abundantly. In this study, we focused on the benthic diatoms from fine sediments covering the sub-tidal bottom of Laguna Guerrero Negro (LGN), located between BCS and BC, a coastal lagoon found half way on the western coast of the BC Peninsula, Mexico.

Initial observations of said sediments suggested that the diatom flora in this location would be highly diverse and that hitherto rare or uncommon taxa recorded in previous studies in the region would be better represented, such as *Lyrella* Karayeva (Bacillariophyceae: Lyrellales). This taxonomic group comprises solely marine species which are commonest in the epipelagic of sandy sediments (Round, Crawford, & Mann, 1990). Species formerly classified as *Navicula* were first allocated in the genus *Lyrella* by Karayeva (1978) based on a single morphological trait, the conspicuous double lyrae. This taxonomic segregation was later justified in depth by Mann and Stickle (1993), showing that their former status as *Navicula* was highly artificial, and currently they represent separate orders.

Although only 53 taxa transferred by D.G. Mann were listed by Round et al. (1990), currently 82 *Lyrella* taxa have been uploaded in the algaebase webpage (Guiry & Guiry, 2015) thus supporting the early expectations by Mann and Stickle (1993) on the diversity of this taxon. Species of the genus *Lyrella* include naviculoid, solitary individuals mostly appearing in valval view. Valve face are flat or slightly undulate with relatively shallow mantles. Frustules are heavily silicified, broadly linear or lanceolate with bluntly rounded or rostrate poles. The raphe system is central and straight. Striae are coarse, uniserial, and are interrupted by a lyre-shaped thickened area of silica, often depressed (Round et al., 1990). Notwithstanding, the similarity with certain naviculales such as *Fallacia* posed the risk of confusion in routine identifications. However, based on the above, the presence of a single plastid in *Fallacia* and 2–4 in *Lyrella*, that justifies their placement in different orders is very helpful to discriminate between them observing fresh material. Also, relying on experience with benthic diatom

taxocoenoses, the strongly silicified frustule of *Lyrella* species projects the double lyrae, that are simulated traits (fallacious) in *Fallacia* species which are mostly small and inconspicuous; with certain exceptions most likely from fresh-water habitats, where *Lyrella* do not occur.

Species of *Lyrella* have been frequently observed in benthos samples from the Baja California Peninsula coasts where they appear conspicuously mainly because of their particularly esthetic forms. However, the variety and abundance of *Lyrella* species may be considered moderately high in certain environments of the region, such as mangrove systems like Magdalena Bay, BCS where 9 *Lyrella* taxa were recorded in a single locality (Siqueiros-Beltrones, López-Fuerte, Hernández-Almeida, & Argumedo-Hernández, 2011). Likewise, 10 *Lyrella* taxa were recorded as epiphytes on macroalgae in the southernmost region of the east coast of the Baja California Peninsula where mangrove forests are common (Siqueiros-Beltrones & Hernández-Almeida, 2006). Furthermore, up to 11 taxa were recorded in a study that comprised 3 mangrove ecosystems of the southern BC Peninsula, and 1 from Sinaloa in mainland Mexico that included tychoplanktonic forms (López-Fuerte et al., 2010). Also, the number of *Lyrella* species recorded in studies on phytoplankton may be as high as in the sediments. For example, Meave-del Castillo, Zamudio-Resendis, Aké-Castillo, Guerra-Martínez, and Barbosa-Ledezma (2003) compiled 11 *Lyrella* taxa records in the tychoplankton of the Mexican Pacific, and Moreno-Ruiz, Licea-Durán, and Santoyo (1996) accounted for 13 *Lyrella* taxa for the Gulf of California. Whilst by comparison Navarro and Hernández-Becerril (1997) compiled 13 taxa records from the highly diverse Caribbean Sea. These accounts set a reference as to the expected species variety in any given area for the genus *Lyrella*.

Earlier, Magdalena Bay was proposed as a “hot spot” for diatom species diversity, in which the high number of *Lyrella* (and *Mastogloia*) taxa marked the difference with other ecosystems in the region (Siqueiros-Beltrones et al., 2011). As stated above our first observations lead us to hypothesize that LGN would harbor a high number of *Lyrella* species and sub-species taxa, in which case this area would fit the denomination of hotspot used in earlier works.

Materials and methods

Laguna Guerrero Negro is located between 27°35' and 27°52' N, 113°58' 114°10' W in the northern- and southernmost parts of BCS and BC, Mexico, respectively (Fig. 1); it is part of a complex along with Laguna Ojo de Liebre, comprised within the Reserva de la Biosfera del Vizcaíno (Arellano-Martínez, De La Cruz-Agüero, & Cota-Gómez, 1996). The lagoons have separate mouths connecting them with Sebastián Vizcaíno Bay. The climate in the region is arid with a low annual rainfall (mostly in winter) of >100 mm (Salinas-Zavala, Llinas, & Rodríguez-Estrella, 1991). LGN is rectangular and extends approximately 2,100 ha, with a length of 13 km, and a maximum width of 8 km, with a narrow channel that opens into Vizcaíno Bay (Contreras, 1985). It has a shallow bottom, mostly between 2 and 12 m (Lluch-Cota, Castellanos-Vera, Llinas-Gutiérrez, &

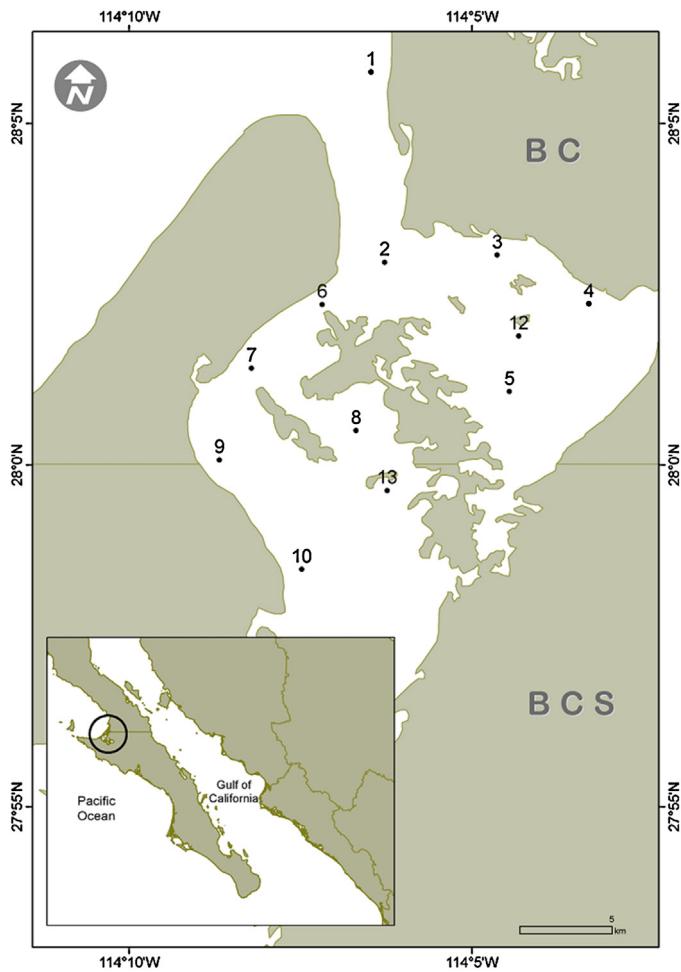

Figure 1. Location of sampling sites for epipelagic diatoms in Laguna Guerrero Negro.

(Ortega-Rubio, 1993), with a maximum depth of 26 m; eel grass is amply distributed from 6 m deep up to high tide level (Eberhard, 1966). Lagoon sediments are composed mainly of gray sand mixed with organic alluvial deposits. Normal salinity gradients, and hypersalinity gradients as well, have been reported (Lankford, 1977), although it has also been considered an iso-haline lagoon; salinity values range from 35.5 to 37.5 (winter), and 34.7–35.6 (summer) (Phleger & Ewing, 1962).

Sediment samples were collected in November (2013), January, March, June, and July (2014) in 12 sites within LGN at depths between 3 and 15 m (Fig. 1). Approximately 150 g of sediments from the upper layer were sampled by scuba diving using a 250 mL plastic jar.

At the laboratory, a subsample was placed in a beaker dissolved with 50 mL of purified water. This was submerged in water contained in the ultrasound bucket and treated with ultrasound for 1 min while agitating gently. Afterwards, sediments were removed by decanting while the remaining fraction was placed in a 100-mL test tube. After 2 h, the overlaying water was decanted in-order-to separate a concentrate of diatom frustules in the bottom of the tube. A subsample from this concentrate was examined under the microscope for observing live diatoms. The rest of the sample was treated with alcohol and nitric acid at a ratio of 1:3:5, adjusting to the amount of organic matter in the

sample (Siqueiros-Beltrones, 2002). After oxidation, the samples were rinsed repeatedly with purified water until reaching a pH ≥6. From each subsample 2 double permanent slides were mounted using the synthetic resin Pleurax (IR = 1.7).

The diatom slides were examined under an optical microscope with phase contrast and planapochromatic optics. Species identification was done based on regional references and basic literature: Hernández-Almeida and Siqueiros-Beltrones (2008, 2012), López-Fuerte et al. (2010), Moreno-Ruiz et al. (1996), Siqueiros-Beltrones (2002, 2006), Siqueiros-Beltrones and Hernández-Almeida (2006), Siqueiros-Beltrones, Argumedo-Hernández, Murillo-Jiménez, and Marmolejo-Rodríguez (2014), Hustedt (1959, 1966), Peragallo and Peragallo (1908), Round et al. (1990), Schmidt et al. (1959), Stidolph, Sterrenburg, Smith, and Kraberg (2012), and Witkowski, Lange-Bertalot, and Metzeltin (2000). All taxa were updated using AlgaeBase (Guiry & Guiry, 2015). An iconographic reference was built using micrographs taken with a CMOS Konus digital ocular lens at 1,000×. Measurements of specimens were done directly with a calibrated micrometric ocular lens, and images were manipulated so esthetically fit the plates according to size (interval when possible).

Results

Out of a floristic list of 232 identified diatom taxa from subtidal sediments of LGN for the sampling period, 21 species and sub-species taxa of *Lyrella* were recorded; most were observed frequently although 6 are hitherto represented only by a single specimen. The *Lyrella* taxa represent less than 10% of the floristic list, however, its diversity is second only to *Amphora* (25), and clearly surpasses previous records, thus supporting our proposal of considering LGN as a hot-spot for *Lyrella* species, at least until further surveys in Mexican coasts are carried out.

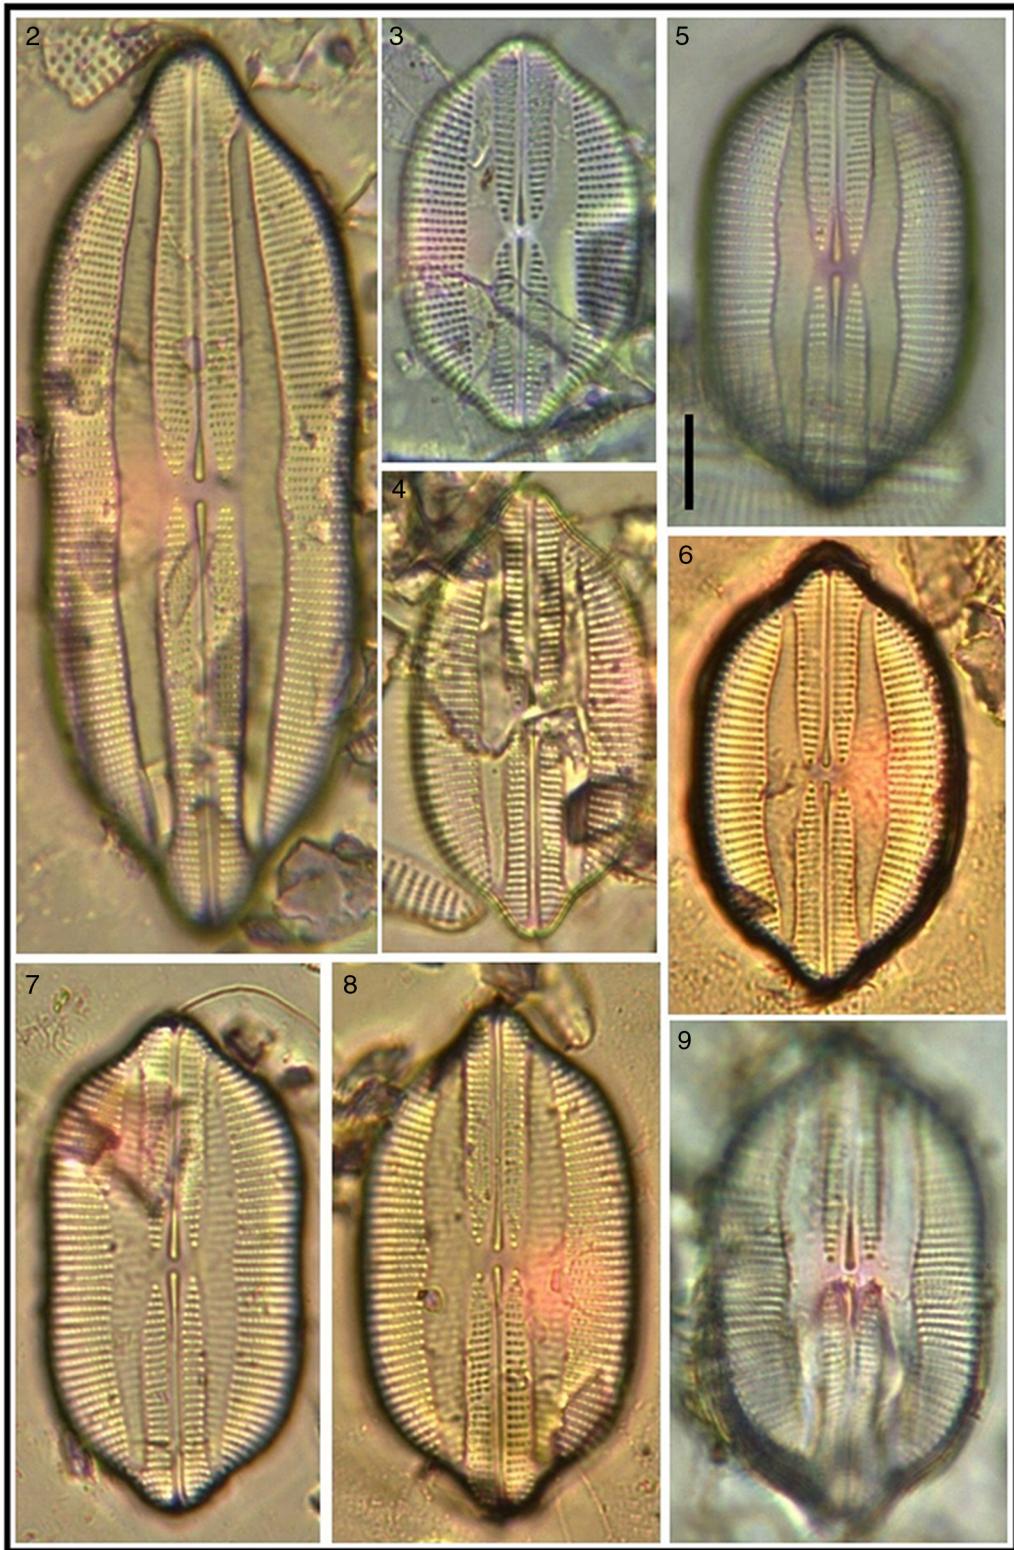

Seven of the *Lyrella* taxa recorded are new for the Mexican coasts, 12 for the NW Mexican region, and 1 for the western coast of the Baja Peninsula. Six taxa had not been transferred from their original genus *Navicula* and are here proposed as new combinations and transferred to the genus *Lyrella*; morphometric and meristic data are included for the identified *Lyrella*. An iconographic reference (Figs. 2–105) is also provided where it is shown that much fine sediment precluded better images of some specimens which were however included to show variation within the taxon.

In what follows, descriptions of the *Lyrella* species and sub-species taxa identified in subtidal sediments of Laguna Guerrero Negro are provided. Twelve are new records for the region (*), 7 for the Mexican coasts (●), and 2 for the W coast of the Baja California Peninsula (**). Six new nomenclatural combinations (comb. nov.) are proposed. Morphometric and meristic data are provided for all taxa.

Earlier referred to as such by Moreno-Ruiz et al. (1996), Sánchez-Rueda (2002), and Martínez-López et al. (2004) as *L. lyra* f. *subtypica*, albeit a formal taxonomic transference was not proposed.

Dimensions: length 70–103 µm, width 30–37 µm, 12 striae in 10 µm ($n=9$).

Reference: Hustedt (1966), Peragallo and Peragallo (1908).

Basionym: *Navicula lyra* var. *subtypica* A. Schmidt. http://www.algaebase.org/search/species/detail/?species_id=q7e8fb0c05459c57c

Synonym: *Navicula lyra* var. *subtypica* A. Schmidt in Hustedt (1966).

Previous records: Gulf of California (Moreno-Ruiz et al., 1996); Gulf of México (Sánchez-Rueda, 2002); off Magdalena Bay (Martínez-López et al., 2004).

Lyrella spectabilis (Gregory) D.G. Mann *

Figure 101

Dimensions: length 62 µm, width 40 µm, 10 striae in 10 µm ($n=1$).

Reference: Hustedt (1966), Stidolph et al. (2012).

Basionym: *Navicula spectabilis* Gregory. http://www.algaebase.org/search/species/detail/?species_id=q7e8fb0c05459c57c

Synonym (homotypic): *Navicula spectabilis* Gregory.

Previous records: Campeche Bay (Stidolph et al., 2012).

Lyrella spectabilis (Gregory) D.G. Mann var. 1*

We refer this as a possible variety due to our specimen is clearly smaller and with a less conspicuous appearance than the former which is more robust.

Figures 98, 99

Dimensions: length 33 µm, width 20 µm, 12–13 striae in 10 µm ($n=1$).

Reference: Desikachary (1989), Lam. 648, fig. 4.

Basionym: *Navicula spectabilis* Gregory. http://www.algaebase.org/search/species/detail/?species_id=q7e8fb0c05459c57c

Synonym (homotypic): *Navicula spectabilis* Gregory.

Previous records: none.

Discussion

In none of the few surveyed areas of the Mexican NW region, nor in other coasts of Mexico for that matter, have so many *Lyrella* species been recorded hitherto. Several of these species occur frequently in the Gulf of California, either as tychoplankton (Moreno-Ruiz et al., 1996), or have been collected directly from the benthos (Hernández-Almeida & Siqueiros-Beltrones, 2012; López-Fuerte & Siqueiros-Beltrones, 2006; López-Fuerte et al., 2010; Siqueiros-Beltrones, 2006; Siqueiros-Beltrones & Morzaria-Luna, 1999; Siqueiros-Beltrones & Sánchez-Castrejón, 1999; Siqueiros-Beltrones et al., 2011). On the other hand, taxa such as *Lyrella approximata* (Greville) D.G. Mann and *Lyrella circumsecta* (Grunow ex A. Schmidt) D.G. Mann (Siqueiros-Beltrones & Hernández-Almeida, 2006), or *Lyrella abruptoides* (Hustedt) D.G. Mann (Siqueiros-Beltrones, 2002) were not found in our samples, although all have been recorded previously further south just within the Gulf of California, with adjoining mangrove forests. Laguna Guerrero Negro is located northward beyond the geographic distribution of mangroves along the western coast of the Baja California Peninsula (González-Zamorano, Nava-Sánchez, León-de la Luz, & Díaz-Castro, 2011).

The variety of *Lyrella* species and sub-specific taxa, and their frequencies in the samples indicate that environmental conditions in LGN promote the high diversity of the genus. Which, along with the 12 new *Lyrella* records for the Mexican NW

region back up the proposal that this area be considered a hot-spot for *Lyrella*. The fact that 6 taxa were represented by a single specimen shows the need for further observations, including other seasons. Current analysis of the whole taxocoenosis as well as continuing sampling during other months (only 4 were surveyed) may yield other *Lyrella* species, or further information on the temporal distribution of those recorded, providing further evidences for comprising this and the rest of the taxa under the hot-spot concept.

It has to be implied that the geographic distributions of the *Lyrella* taxa recorded here are also extended. In this subtropical zone, the possible influence of tropical waters in the area has been underlined by Hernández-Rivas, Jiménez-Rosenberg, Funes-Rodríguez, and Saldíerna-Martínez (2000), albeit the California Current and regional upwelling events stand out in the region. The low temperature water they provide correlate with certain characteristic biota recorded by Eberhard (1966), which is found also in San Quintín bay and Punta Banda estuary further north in Baja California. This may be defining a transitional zone as proposed earlier by Dawson (1960) and observed later in the structure of phytoplankton assemblages (Gárate-Lizárraga & Siqueiros-Beltrones, 1998) for the Magdalena Bay lagoon complex. All this may also be used to explain the presence of *Lyrella* species from tropical, subtropical and temperate regions. Furthermore, López-Fuerte, Siqueiros-Beltrones, and Yabur (2015) observed a particular benthic diatom flora in Isla Guadalupe, located further north off the west coast of Baja California for which a biogeographical affinity could not be established, with many tropical species (*Mastogloia* spp.) including recent records from the Caribbean Sea. Likewise, the transitional nature of the oceanographic region would be expected to influence the temporal occurrence of certain *Lyrella* species. However, particular environmental characteristics will determine whether these remain as permanent residents of LGN or not.

From another angle, the transfer of the six *Navicula* taxa to *Lyrella* in this paper is an example of the general inertia caused by the establishment of new genera. At first, taxa are rapidly included but process slows down gradually until new surveys record the remaining taxa, as is presented here as a side effect of a floristic effort. As it turns out, identification of diatom species and construction of floristic lists is a still much needed activity that is improving on the basis of comprehensive taxonomic works that incorporate the latest advances in diatom systematics. In this case our contribution is possible because of the combined work of Guiry and Guiry (2015), Hustedt (1959), Karayeva (1978), Mann in Round et al. (1990).

In spite of the above, identification of diatom species and sub-species taxa poses much difficulty and always will. Although *Lyrella* species are conspicuous some difficulty exists especially for the untrained eye when certain *Fallacia* taxa appear in the samples, and certain experience with benthic diatom taxocoenoses is required to readily discriminate between these genera relying on the taxonomic traits exposed earlier. Moreover, trying to discern between certain *Lyrella* species or sub-species taxa may imply an important degree of uncertainty. An example is the raphe valve of *Cocconeis californica* var. *kerguelensis* Heiden, initially mistaken for *Lyrella* and then *Craspedopleura*

(Figs. 66 and 67). This happens particularly in the traditional practice of identifying diatoms from samples that yield over 150 species and resorting to several taxonomic references. An example is the nine *Lyrella* from Magdalena Bay (Siqueiros-Beltrones et al., 2011) which were reduced from 15 that were recorded earlier (López-Fuerte & Siqueiros-Beltrones, 2006). Also, because in this study we focused solely on diatoms of the *Lyrella* group it was expected that a more efficient discrimination of the taxa be done, thus resulting in the higher number of species and sub-specific taxa here recorded. In this case, our floristic effort yielded 12 new records for the region although only samples for 4 months were surveyed. It is thus evident that the lack of floristic studies on benthic diatoms in much of the Mexican coasts precludes insight of their ecology and distribution. However, continuous floristic surveys should allow precise definition of biogeographic affinities of benthic diatom flora in the coasts of Mexico.

Acknowledgements

This study was financed by project SIP-20150537, Instituto Politécnico Nacional. We appreciate advice given by Sylvia Sala, Nelson Navarro, Eberto Novelo and Oscar Romero on formal taxonomy of diatoms. DASB is COFAA and EDI fellow of the IPN. FOLF currently holds a postdoctoral research grant from Conacyt. The reviews by 2 anonymous referees helped to improve this manuscript.
